

## Create Application Like Gmail (Front end only)

### Instructions for Application

There is no need to make backend logic for the project, just imitate a network call and use static data. For example, all received mails may be saved in a variable (in json), which can be displayed when user clicks on Inbox. This project judges the ability to create flow and functionalities in an app.

- 1.Create simple login form. (all credentials will work as there is no backend)
- 2.Your Email App should contain Inbox,Sent,Drafts,Trash boxes.
- 3.App should contain compose email option.
- 4.Compose email should contain to,subject,body,attachments.
- 5.User can enter the multiple recipients in to field.
- 6.Don't allow the user to send email without filling to option.
- 8 make the difference between read,unread emails in boxes like gmail.
9. Make a UI to show conversation thread like Gmail. You can have static data but implementation must be dynamic.

See below

## **Programming Instructions**

1. Use any framework, plugin or IDE you want.
4. Write Optimized code.
5. Don't worry much about how it looks. Focus mainly on functionality.
5. Don't get any project like this from online you will have to answer for some questions on what you have done.
6. Let us know if you have any doubts.
